004 (part 1 of 1) 6 points
Assume that five weak acids, identified only by numbers ( $1,2,3,4$ and 5 ), have the following ionization constants.

| Acid | Ionization <br> Constant <br> $K_{\mathrm{a}}$ value |
| :---: | :---: |
| 1 | $1.0 \times 10^{-3}$ |
| 2 | $3.0 \times 10^{-5}$ |
| 3 | $2.6 \times 10^{-7}$ |
| 4 | $4.0 \times 10^{-9}$ |
| 5 | $7.3 \times 10^{-11}$ |

The anion of which acid is the weakest base?

## 1. 1 correct

2. 2
3. 3
4. 4
5. 5

## Explanation:

$$
\begin{aligned}
& \mathrm{HA} \rightleftharpoons \mathrm{H}^{+}+\mathrm{A}^{-} \\
& K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{H}][\mathrm{A}]}
\end{aligned}
$$

The 'anion of an acid' is another way of saying 'conjugate base,' and a weak conjugate base corresponds to a strong acid. So really what we're looking for is which acid is strongest (has the lowest pH ).

A low pH means that the $\left[\mathrm{H}^{+}\right]$concentration is low. (Remember that values greater than 7 are basic!) The larger values of $K_{\mathrm{a}}$ means that there is more $\left[\mathrm{H}^{+}\right]$so you would expect these solutions to be more acidic; i.e., have smaller pH 's. The smaller $K_{\mathrm{a}}$ values mean less $\left[\mathrm{H}^{+}\right]$in solution, so higher pH 's. The acid with the largest $K_{\mathrm{a}}(\# 1)$ will have the lowest pH ; i.e., highest $\left[\mathrm{H}^{+}\right]$concentration
